

2] How are joins used to combine data from multiple tables?

Ans:

1. Identify Common Columns:

Tables must have at least one column in common (called a "key").

These columns act as a bridge between the tables.

2. Join Conditions:

Use the ON clause to specify how rows from one table relate to rows in the other table (e.g., table1.column = table2.column).

3. Combine Rows:

SQL evaluates each row from the first table against rows in the second table.

Based on the type of join, SQL decides which rows to include in the result.
